

1. An interesting aspect found through the data sample was that it was a near even split between male and female sex for the mice regarding the testing for these anti-cancer pharmaceuticals. I am sure the reasoning behind this was to take as many similar mice as possible to ensure as unbiased of an evaluation as possible.
2. During this study the recommendation would be to go with Ramipril over Capomulin only by a slight margin as both their means reduced the tumor volume at almost the same size.
3. The drugs that should least be considered as candidates to reduce tumor volume based on these results would be Naftisol, Ketapril, and Stelastin. These three drugs mean on tumor reduction was less than the placebo which as a barometer should not make it to be a candidate for further research in anti-cancer medicine.
